

Child Disability and Parental Labor Supply

João Garcia, Rafael Latham-Proença, Marcela Mello and Joana Silva

October 7, 2025

Policy Research Workshop: Women and Jobs in Latin America and the Caribbean

- Severe child disability creates a double burden on parents:
 - higher needs both time and financial resources
- In developing countries informality offers flexibility, but research is scarce
- Challenges:
 - Data on informality is rare
 - Endogeneity of child disability

- Study the 2015 zika virus outbreak in Brazil
- Unexpected nature addresses endogeneity
- Data on informal labor
- Results:
 - Parents' employment, formal and informal
 - Household Income
 - Family composition
 - The role of social assistance programs

Background

Background

- Spike in CZS cases in Brazil starting in mid-2015
- CZS is a severe disability, requires therapy and care
- Public health measures start around December 2015

- Role of preventive behaviors was minimal. **CZS was unknown.** Infections are more likely to cause CZS during the first trimester.
- Selective abortion and fertility responses unlikely.
- No direct effect on the mother.
- Mortality is high. We work with a sample with low mortality and check sensitivity.

Data

- **RESP-Microcefalia**
 - Record of all cases of CZS
- **RAIS**
 - Track all formal employees over time
- **Single Registry**
 - Recipients of any government program: bottom half of population
 - Source on family structure and informal work.

Empirical Strategy

Identification Strategy

- We need to control for **time** and **place** of birth, to address environmental risk of contagion, and **individual risk factors**.
- We use exact matching based on:
 - a) Municipality of residence
 - b) Month of birth
 - c) Maternal age,
 - d) Education (completed high school)
 - e) Parity (firstborn)
 - f) Race (white)
- Based on epidemiological literature and balance checks.

Balance table

Matching details

Fully saturated model event-time model:

$$y_{i\tau} = \sum_{k \in \kappa} \mu_k 1\{\tau = k\} + \sum_{k \in \kappa} \beta_k 1\{\tau = k\} \cdot T_i + \varepsilon_{i\tau}$$

- μ_k : average in period k for control
- β_k : average difference for treated .
- **Weights**: Treated units receive a weight of 1 and all control units a weight of $\frac{n_t(s)}{n_c(s)}$
- **Results**: difference over time, average difference, DID average

Social Assistance

Household Income by Source

- BPC: social security program – one minimum wage to poor disabled people.
- Important to understand heterogeneity of effects based on recipient status.
 - Income effects may be important, as well as employment disincentives.
- We analyze heterogeneity interacting CZS with the BPC.
- We estimate the propensity score of receiving the BPC and control for it, and its interaction with CZS.
 - Controls for heterogeneity in characteristics that determine recipient status.

Heterogeneity by Family Structure

Effect on Mother's Formal Employment

Effect on Mother's Informal Employment

Conclusion

- We exploit the Zika shock to study the effects of child disability.
- Strong negative effects for mothers in formal employment.
- Strong effects on informal labor challenge the notion that informality serves as a buffer.
- Social disability payments seem crucial in buffering family income, but reduce employment
- We find no effects in family structure.
- Single mothers have larger reductions in informal employment but not in the formal sector.

Appendix

Stage	Cases
<i>A. Initial Sample Construction</i>	
RESP records (probable/confirmed CZS)	3,594
After dropping missing birth dates	2,946
After restricting to 2015 – 2017	2,431
After de-duplication	2,411
